# Vorwort.

---

Die vorliegenden Tafeln für die hellen Fixsterne bis zur 3. Größe, deren Abweichung größer als  $30^{\circ}$  N ist, bilden die Ergänzung der im Jahre 1913 herausgegebenen Tafeln für Gestirne, deren Abweichung kleiner als  $\pm 30^{\circ}$  ist. Ihr Zweck ist die für die Zeichnung der Standlinie in den stereographischen Karten zur astronomischen Ortsbestimmung für  $55^{\circ}$  Breite nötigen Größen ohne lästiges und umständliches Einschalten und Nebenrechnungen zu liefern. Die Tafeln sind bestimmt für ein Gebiet zwischen den Breitenparallelen  $50^{\circ}$  und  $60^{\circ}$ . Jede Seite der Tafeln enthält die Höhen und die Azimute für einen Stern und für drei volle Stunden des zugehörigen Stundenwinkels in Zwischenräumen von einer Minute, außerdem die zugehörigen Schalttafeln für jede sechste Sekunde des Stundenwinkels. Die Schaltteile sind so klein, daß sie bequem im Kopfe zu den der Haupttafel entnommenen Höhen und Azimuten unter Berücksichtigung ihres Vorzeichens hinzugefügt werden können. Das weitere Einschalten innerhalb der Schalttafeln darf in der Praxis vernachlässigt werden, da dadurch höchstens ein Fehler von  $\frac{1}{2}'$  in der Höhe verursacht werden kann. Da alle Werte auf einer Seite nebeneinander stehen, wird Umblättern und zeitraubendes Suchen vermieden.

Die Höhen sind für jede vierte Minute des Stundenwinkels unter Benutzung siebenstelliger Logarithmen und sechsstelliger Tafeln der natürlichen Sinus berechnet worden. Bei der Rechnung wurden die Abweichungen der Fixsterne für Mitte 1917 zu Grunde gelegt. Da sich die Abweichung jährlich höchstens um  $0:33$  ändert, also in  $2\frac{1}{2}$  Jahren um  $0:8$ , so können die Tafeln mit genügender Genauigkeit für den Zeitraum von 1915 bis 1920 benutzt werden. Am Fuße jeder Seite sind die der Zu- oder Abnahme der Abweichung entsprechenden Aende-

rungen in Höhe und Azimut für die Jahre 1920—25, 1925—1930, 1930—1935 angegeben, sodaß die Tafeln 20 Jahre Giltigkeit haben. Zur Erleichterung der Berechnung des Stundenwinkels ist ferner die Gerade Aufsteigung des Sternes und ihre jährliche Änderung auf jeder Seite vermerkt. Um schnell passende Sterne zur Beobachtung auswählen zu können, ist auf Seite 1 die mittlere Ortszeit der Kulmination der Sterne für den ersten jeden Monats enthalten.

Die Azimute sind den amerikanischen Azimuttafeln für jede zehnte Minute des Stundenwinkels durch Einschalten entnommen. Wo sicheres Einschalten nicht gewährleistet oder zu zeitraubend ist, wurden die Azimute für jede vierte Minute des Stundenwinkels auf Hundertstel Grad neu berechnet. Die Zwischenwerte in Höhe und Azimut wurden durch zweimaliges Einschalten in die Mitte unter Berücksichtigung zweiter Differenzen gewonnen.

Die Berechnung und Drucklegung lag in den Händen des ständigen Mitarbeiters der Deutschen Seewarte Dr. Wedemeyer. Mitteilungen über aufgefundene Fehler oder Hinweise auf Verbesserungen der Tafel werden mit Dank entgegengenommen.

Berlin, im Januar 1916.

# Anleitung zum Gebrauch der Tafel.

---

Aus der Tafel entnimmt man die zur Zeichnung der astronomischen Standlinie in der Karte erforderlichen Größen, d. i. Höhe und Azimut des Sternes in der Kartenmitte. Als Eingang dient der Stundenwinkel des Mittelmeridians. Dieser Stundenwinkel wird mit Hilfe der Frühlingspunkts-Ortszeit (Fp. O. Z.) des Mittelmeridians gefunden. Am einfachsten ist es, diese Zeit einer nach Frühlingspunkt-Zeit gehenden Uhr zu entnehmen. Deshalb ist eine solche Uhr als zweite Beobachtungsuhr an Bord der Luftschiffe gegeben worden. Bei Beobachtungen von Sternen benutzt man daher diese und nicht die nach mittlerer Zeit gehende Beobachtungsuhr.

**Ermittlung des Stundenwinkels. Uhr nach Frühlingspunkts-Zeit.** Ist Fp. Z. die Frühlingspunkts-Zeit, die man durch Anbringen des Uhrstandes an die Ablesung U der Fp. Z.-Uhr erhält und  $\alpha$  die Gerade Aufsteigung des Sterns, so ist

$$t = \text{Fp. Z.} - \alpha.$$

Ist die Gerade Aufsteigung kleiner als die Frühlingspunkts-Zeit, so ist der Stundenwinkel westlich ( $t_w$ ), ist sie größer, so ist der Stundenwinkel negativ oder östlich ( $t_o$ ). Der Eingang in die Tafel ist in beiden Fällen der gleiche. Der Wert von  $\alpha$  ist für jeden Stern unten links auf jeder Seite angegeben. Er gilt für 1917. In anderen Jahren ist die ebenfalls angegebene jährliche Änderung dieser Größe bei der Entnahme zu berücksichtigen. Es ist zu beachten, daß das Zifferblatt der Uhr nur die Stunden 1 bis 12 anzeigt, während die Fp. Z. bis 24<sup>h</sup> gezählt wird. Zu der Uhrablesung sind daher gegebenenfalls 12 Stunden zuzuzählen.

Im allgemeinen wird die Beobachtungsuhr nach mitteleuropäischer Frühlingspunktszeit gehen, da in Deutschland die mitteleuropäische Zeit gesetzliche Zeit ist. Ist dies der Fall, so kann die Uhrablesung ohne weiteres zur Berechnung des Stundenwinkels benutzt werden, wenn man sich im Bereich der Ostsee-Karte befindet, da der Mittelmeridian dieser Karte der mitteleuropäische Meridian, d. h.  $15^{\circ}$  Ost von Greenwich ist.

Befindet man sich dagegen im Bereich der Nordsee-Karte, deren Mittelmeridian der Meridian von Greenwich ist, so ist nicht die mitteleuropäische Frühlingspunkts-Zeit, sondern die Greenwicher Frühlingspunkts-Zeit zur Berechnung des Stundenwinkels zu benutzen. Sie ist gegenüber der mitteleuropäischen Fp.-Zeit um eine Stunde zurück; von der Ablesung der nach M. E. Fp. Z. gehenden Uhr ist daher 1 Stunde in Abzug zu bringen, wenn man Gr. Fp. Z. haben will.

**Uhr nach mittlerer Zeit.** Ist die Beobachtung nicht nach einer Fp. Z.-Uhr, sondern nach einer mittleren Zeituhr gemacht, so ist der Stundenwinkel ( $t$ ) nach folgender Formel zu berechnen:

$$t = m. Z. + m. \odot \alpha - * \alpha.$$

$m. \odot \alpha$  ist die Gerade Aufsteigung der mittleren Sonne. Sie ist für den mittleren Greenwicher Mittag auf der Seite II eines jeden Monats im Nautischen Jahrbuch angegeben. Zwischen den angegebenen Werten ist für den Zeitpunkt der Beobachtung einzuschalten.

Im Gebiete der Ostsee-Karte ist als  $m. Z.$  die mittlere mitteleuropäische Zeit (M.E.Z.), im Gebiet der Nordsee-Karte die mittlere Greenwicher Zeit (m. Gr. Z.) zu benutzen. Bei der Berechnung des Stundenwinkels ist auch die mittlere Zeit von  $0^{\text{h}}$  bis  $24^{\text{h}}$  zu zählen und zwar von Mittag bis Mittag. Kommt ein Stundenwinkel über  $12^{\text{h}}$  heraus, so ist er von  $24^{\text{h}}$  abzuziehen, wodurch man den östlichen Stundenwinkel ( $t_6$ ) bekommt.

**Ermittlung von Höhe und Azimut.** **Errechnete Höhe.** Mit der Stunde und der vollen Minute des Stundenwinkels, also vorläufig unter Vernachlässigung der Anzahl Sekunden, entnimmt man der Tafel die Werte der Höhe ( $h_o$ ) und des Azimutes ( $Az_o$ ). Aus der rechts danebenstehenden Schalttafel entnimmt man die Verbesserungen in Höhe ( $\Delta h$ ) und Azimut ( $\Delta A$ ), wobei man diejenige Anzahl Sekunden, die den zuvor vernachlässigten Sekunden des Stundenwinkels am nächsten liegt, als Eingang benutzt. Die Werte  $\Delta h$  und  $\Delta A$  fügt man unter Berücksichtigung ihres Vorzeichens den entnommenen Tafelwerten  $h_o$  und  $Az_o$  hinzu.

Dadurch erhält man die für den Kartenmittelpunkt geltenden berechneten Werte von Höhe ( $h_r$ ) und Azimut ( $Az_r$ ).

Das Azimut ist dabei, wie in Ebsen's Azimuttafeln, von Nord über Ost oder West bis  $180^{\circ}$  gezählt, je nachdem der Stundenwinkel des Sternes östlich oder westlich ist.

**Beobachtete Höhe.** Die am Sextanten abgelesene Höhe ( $h_a$ ) wird durch Anbringung der Indexverbesserung (I. V.) und der Gesamtverbesserung (G. V.) auf die wahre oder beobachtete Höhe ( $h_b$ ) beschickt,

$$h_b = h_a + I. V. + G. V.$$

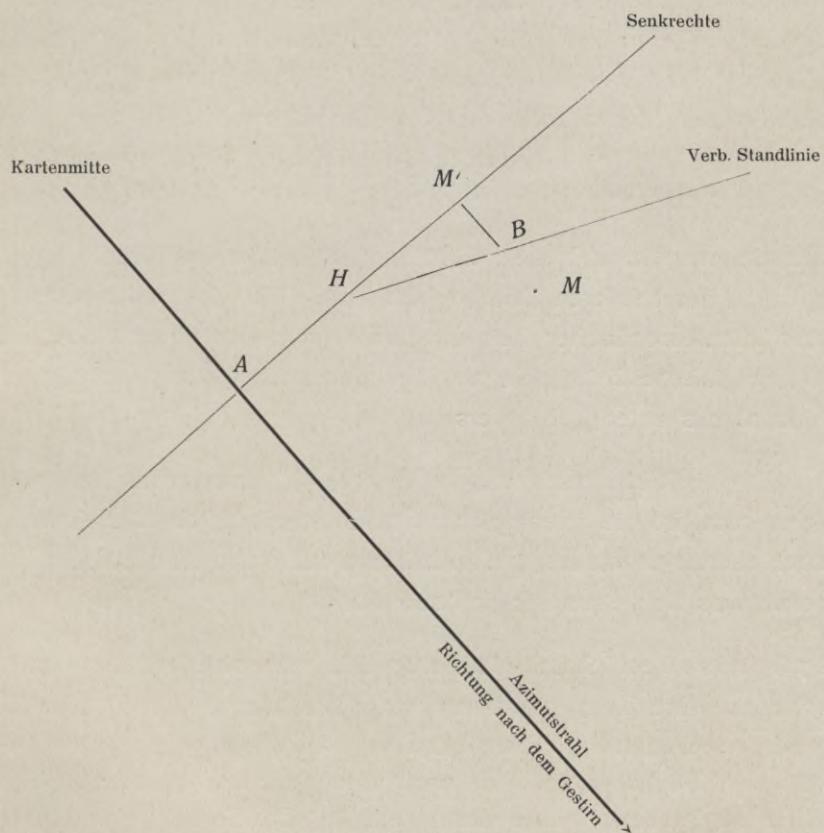

**Höhenunterschied.** Zur Zeichnung der Standlinie hat man schließlich den Höhenunterschied

$$\Delta h = h_b - h_r$$

zu bilden

**Standlinie.** Durch den Kartenmittelpunkt zieht man in der durch  $Az_r$  angegebenen Richtung mit Hilfe des Azimutkreises der Karte und des Lineals oder Dreiecks eine gerade Linie, die Azimutstrahl heißen möge. Dieser Azimutstrahl gibt die Richtung nach dem Gestirn an. Auf ihm wird vom Kartenmittelpunkt aus der Höhenunterschied  $\Delta h$  abgetragen und zwar in der Richtung nach dem Gestirn hin, wenn  $\Delta h$  positiv ist, in der Richtung vom Gestirn fort, wenn  $\Delta h$  negativ ist. Zum Abtragen von  $\Delta h$  enthalten Absetzlineal und Dreieck eine Teilung nach Graden und Minuten im Maßstab der Karten.

Durch den Endpunkt des abgetragenen Höhen-Unterschiedes wird mit Hilfe des Dreiecks eine zu dem Azimutstrahl senkrechte Linie gezogen. In der Nähe des Azimutstrahls liegt diese Linie so nahe an der Höhengleiche, auf der sich der Schiffsort befinden muß, daß sie als Standlinie für das Schiff angesehen werden kann. In größerem Abstande von dem Azimutstrahl biegt die Höhengleiche etwas von der eingezeichneten Senkrechten ab und zwar in der Richtung nach dem Gestirn hin. Der Betrag dieser Abweichung ist aus der Tabelle „Abweichung der Höhengleiche von der Geraden in der stereographischen Karte“

(Seite 11) zu ersehen. In denjenigen Fällen, wo diese Abweichung nicht zu vernachlässigen ist und die gezeichnete Senkrechte nicht als Standlinie genügt, kann eine zweite Standlinie folgendermaßen gezeichnet werden.

Man mißt mittels der Teilung auf Lineal oder Dreieck den Abstand des mutmaß-

lichen Schiffsorts (M) vom Azimutstrahl. Mit diesem Abstand und der beobachteten Höhe entnimmt man der Tabelle der Abweichungen die zugehörige Abweichung und trägt sie von M' aus parallel zum Azimutstrahl in der Richtung nach dem Gestirn hin ab. In der Figur sei dies M'B. Den Punkt M' findet man dadurch, daß AM' gleich dem Abstande des mutmaßlichen Schiffsortes M vom Azimutstrahl ist. Die Strecke AM' wird in H halbiert. Es genügt, diese Halbierung nach dem Augenmaß zu machen. Dann zieht man durch H und B eine Gerade. Dies ist die verbesserte Standlinie.

In der Karte für die Ostsee sind die Längen nicht von Greenwich, sondern vom Mittelmeridian aus östlich und westlich gezählt. Beim Eintragen des Schiffsortes ins Tagebuch muß man daher die auf der Karte abgelesene Länge, wenn sie östlich vom Mittelmeridian ist, zu  $15^{\circ}$  hinzuzählen; wenn sie westlich ist, von  $15^{\circ}$  abziehen, um Greenwicher Länge zu erhalten.

**Uhrvergleich.** Die Anwendung der astronomischen Ortsbestimmung setzt voraus, daß man über den Stand der Beobachtungsuhrn unterrichtet ist. Meist wird der Gang dieser Uhren so klein sein, daß er vernachlässigt werden kann, wenn vor dem Antritt der Fahrt oder während ihr eine Standbestimmung gemacht wird. Wenn eine Uhr dagegen einen erheblichen Gang haben sollte, so wird er für die Zwischenzeit zwischen Standbestimmung und Beobachtung berücksichtigt werden müssen. Es empfiehlt sich in solchen Fällen die Uhr möglichst bald umzutauschen.

Die Standbestimmung kann mittels F.T. oder telephonisch erfolgen. In beiden Fällen wird zunächst der Stand der mittleren Zeituhr bestimmt. Die Großfunkenstation Norddeich gibt 1 Uhr mittlerer Mitteleuropäischer Zeit (= 12 Uhr mittlerer Greenwicher Zeit) mittags und nachts funkentelegraphische Zeitsignale ab, über deren Einrichtung das Nähere aus Tafel 15 des Nautischen Jahrbuchs unter I. 1 zu ersehen ist.

Während daher die Standbestimmung mittels F. T. nur zweimal täglich, mittags und mitternachts, erfolgen kann, ist die telephonische Standbestimmung an Land jederzeit ausführbar. Es wird dabei allerdings vorausgesetzt, daß man den Stand der mittleren Uhr auf etwa 5 Minuten genau kennt, was wohl stets der Fall sein dürfte.

Zur telephonischen Standbestimmung läßt man sich mit der Stationszentrale Wilhelmshaven verbinden. Ihre Telephonnummer ist: Wilhelmshaven Nr. 2000 bis 2019. Nachdem sich die Zentrale gemeldet hat, verlangt man Nr. Null, Zeitsignal, und wartet (mit dem Hörer am Ohr) bis das Zeitsignal ertönt. Es wird von einer auf dem Kaiserlichen Observatorium aufgestellten Uhr in jeder Minute einmal erteilt. Das Signal besteht aus einem im Hörrohr des Fernsprechers deutlich wahrnehmbaren sirenartigen Tone, der in jeder Minute genau von der Sekunde 55,0 bis zur Sekunde 60,0 mittlerer mitteleuropäischer Zeit ertönt, sodaß das Ende des Tones der vollen Minute entspricht. Nach kurzer Pause folgen die Kennungstöne, die die Minutenzahl kennzeichnen. Die Kennungstöne setzen sich aus kurzen Schnarrtönen (●) und einem zwei Sekunden dauernden Sirenenton (—) nach dem folgenden Schema zusammen.

Bei Minute 1 ertönt: ●

„ „ 2 „ : ●● .  
„ „ 3 „ : ●●●  
„ „ 4 „ : ●●●●  
„ „ 5 „ : ●●●●●  
„ „ 6 „ : ● —  
„ „ 7 „ : ●● —  
„ „ 8 „ : ●●● —  
„ „ 9 „ : ●●●● —  
„ „ 10 „ : ●●●●● —

Bei der vollen Stunde „ : ——————

Abgesehen von der vollen Stunde wiederholen sich also alle 10 Minuten dieselben Kennungen, woraus sich die Notwendigkeit ergiebt, bei Benutzung des telephonischen Zeitsignals die mitteleuropäische Zeit auf etwa 5 Minuten genau zu kennen. Um Verwechslungen, namentlich zwischen Minute 1 und 6, zu vermeiden, muß man nach dem letzten Schnarrton das Hörrohr noch 5 Sekunden am Ohr behalten.

Während des anderen Teiles der Minute ertönt zum Zeichen, daß die Verbindung mit dem Zeitsignal ausgeführt ist, beständig ein regelmäßiges Knacken im Hörrohr. Die Schnarrtöne und das regelmäßige Knacken werden, wenn der Hörapparat weit von Wilhelmshaven entfernt ist, leicht überhört, so lange das Ohr nicht an solche Zeichen gewöhnt ist. Es dürfte sich daher empfehlen, den Uhrvergleich zur Kontrolle einige Zeit später nochmals zu wiederholen.

Eine telephonische Standbestimmung wird demnach etwa folgendermaßen verlaufen. Sobald die Verbindung mit Nummer Null der Zentrale hergestellt ist, richtet man (mit dem Hörrohr am Ohr) den Blick auf den Sekundenzeiger der m. Z.-Beobachtungsuhr, bis der sirenentartige Ton von Sekunde 55,0 bis Sekunde 60,0 ertönt. Man beobachtet die Sekunde, die der Zeiger der Uhr im Augenblick des Aufhörens des Tons anzeigt und schreibt diese Sekunde sofort auf ein Blatt Papier nieder. Dann beobachtet man die Minutenkennung der Werftuhr und schreibt sie unter Hinzufügung der Sekundenzahl 0<sup>s</sup> über die Angabe der Beobachtungsuhr. Die letztere wird dann durch Vorsetzen der hinzugehörigen abgelesenen Minutenzahl vervollständigt. Durch Abziehen der Angabe der Beobachtungsuhr von der Werftuhr bekommt man schließlich den Stand der Beobachtungsuhr.

Beispiele:

Werftuhr: . . m. M. E. Z. = 9<sup>m</sup> 0<sup>s</sup>  
Beobachtungsuhr: U = 11 43  
Uhrstand: . m. M. E. Z. — U = — 2 43

Werftuhr: . . m. M. E. Z. = 53<sup>m</sup> 0<sup>s</sup>  
Beobachtungsuhr: U = 49 18  
Uhrstand: . m. M. E. Z. — U = + 3 42

Bekommt man keinen Anschluß an die Stationszentrale Wilhelmshaven, so kann man das völlig gleichartige Zeitsignal der Hamburger Sternwarte benutzen, das unter der Nummer Hamburg Gruppe 4 Nr. 10 000 anzurufen ist.

Der Stand der Fp. Z.-Uhr wird durch Vergleich mit der m. Z.-Beobachtungsuhr ermittelt. Man stellt die Angaben der beiden Uhren fest, die für einen bestimmten Zeitpunkt einander entsprechen. Die Angabe der m. Z.-Uhr wird durch Hinzufügen des Uhrstandes in mittlere Zeit verwandelt. Die mittl. Zeit ist dabei von Mittag zu Mittag von 0<sup>h</sup> bis 24<sup>h</sup> zu zählen. Aus dem Nautischen Jahrbuch entnimmt man Gerade Aufsteigung der mittleren Sonne (m.  $\odot\alpha$ ), wobei man für den Zeitpunkt des Uhrvergleichs einschaltet. Durch Hinzufügen von m.  $\odot\alpha$  zu der mittl. Zeit bekommt man die Frühlingspunkts-Zeit des Zeitpunktes des Uhrvergleichs. Indem man schließlich die Angabe der Fp. Z.-Uhr von der so ermittelten Frühlingspunkts-Zeit abzieht, erhält man den Stand der Fp. Z.-Uhr.

Beispiel:

m. Z. U = 10 18 11 Vm am 20. Jan.	m. Gr. Z. = 21,26 <sup>h</sup>	m. $\odot\alpha$ am 19. Jan. = 19 <sup>h</sup> 50 <sup>m</sup> 14 <sup>s</sup>
= 22 18 11 am 19. Jan.	Aend. = 21,3 × 9,9 <sup>s</sup>	Aend. = + 3 31
m M.E.Z.U = — 2 43	= 211 <sup>s</sup> = 3 <sup>m</sup> 31 <sup>s</sup>	m. $\odot\alpha$ = 19 53 45
m. M E. Z. = 22 15 28		
m. $\odot\alpha$ = 19 53 45		
M. E. Fp. Z. = 18 9 13		
Fp. Z. U = 18 13 0		
M. E. Fp. Z. - U = — 3 47		

---

### Beispiel:

Am 15. September 1916 beobachtete man um 2<sup>h</sup> 18<sup>m</sup> 19<sup>s</sup> Vm am Chronometer  $\text{※ Capella} = 62^{\circ}37'$ , Augeshöhe 5 m. Das U-Boot befindet sich im Skagerrak.

m. Gr. Z. = 14<sup>h</sup> 18<sup>m</sup> 19<sup>s</sup> den 14. Sept.

Nautisches Jahrbuch S. 115

m.  $\odot\alpha$  am 14. Sept. = 11<sup>h</sup> 32<sup>m</sup> 31<sup>s</sup>

m. $\odot\alpha$ = 11 34 53	$\text{※} = 62^{\circ}37'$	Aend. = 14,3 × (10-0,1) <sup>s</sup> = 2 22
Fp. Z. = 1 53 12	Ges. Verb. = -4	m. $\odot\alpha$ = 11 34 53
$\alpha$ Capella = 5 10 31	$h_b = 62^{\circ}33'$	Seite XI der Anleitung.
$t_{\delta}$ = 3 17 19	$h_r = 58^{\circ}3' \text{ [Seite 27 der Tafel]}$	Abstand vom Azimutstrahl = 3 <sup>o</sup>
	$\Delta h = +4^{\circ}30' \text{ N } 85,5^{\circ} \text{ O.}$	$h_b = 62^{\circ}30'$
		Abw. d. Höhengleiche = 9 Sm

Im Azimut N 85,5<sup>o</sup> O ist der Azimutstrahl zu ziehen und auf ihm nach dem Gestirn hin die Strecke von 4<sup>o</sup> 30' abzutragen. Im Endpunkt wird eine Standlinie senkrecht zum Azimutstrahl gezogen. Im Abstand 3<sup>o</sup> setzt man die kleine Strecke von 9' an der dem Gestirn zugekehrten Seite ab und zieht durch den Endpunkt und den Punkt 1<sup>o</sup> 30' der ersten Standlinie (Mitte von 3<sup>o</sup>) die zweite Standlinie. Die beiden Standlinien gehen durch die Punkte auf nebenstehendem Täfelchen, die zur Kontrolle dienen können.

58 <sup>o</sup> N 8 <sup>o</sup> 20' O
57 8 2
56 7 53
55 7 50
