ERLÄUTERUNG

DES

GEBRAUCHS DER HÜLFS-TABELLEN.

Die folgenden Hülftafeln dienen dazu, um aus den Höhen der Aufträge oder den Tiefen der Abträge den körperlichen Inhalt der betreffenden Dämme, beziehungsweise Einschnitte, für jede Kronen- oder Sohlenbreite und für jede Böschung schnell und genau zu ermitteln. Unmittelbar findet deren Anwendung unter der Voraussetzung Statt, dass die Neigungen der natürlichen Bodenfläche, in rechtwinkliger Richtung auf die Längensaxe, von der Horizontale so wenig abweicht, dass die daraus entspringende Differenz für den Inhalt unbeachtet bleiben kann.

Wie diese Tafeln aber auch in den Fällen benutzt werden können, wenn dieser Querabhang der Bodenfläche so stark ist, um bei der Inhalts-Ermittelung berücksichtigt werden zu müssen, wird weiter unten nachgewiesen werden.

Jeder, im Querschnitt trapezförmige Damm oder Einschnitt lässt sich in drei Körper zerlegen, einen mittleren, welcher ein Parallelepipedum oder einen abgekürzten Keil bildet und zwei Seitenkörper, von denen jeder ein dreiseitiges Prisma, oder eine abgekürzte Pyramide darstellt, je nachdem die Krone des Dammes, oder die Sohle des Einschnitts, der natürlichen Bodenfläche parallel liegt oder nicht.

Der Inhalt des Mittelkörpers ist, wenn a die beständige Kronen- oder Sohlenbreite, h und h' die Höhen oder Tiefen an beiden Enden l die Länge des Körpers, n die Verhältniss-Zahl der Böschung bezeichnet.

$$= \left[a \cdot h' + a \cdot \left(\frac{h-h'}{2} \right) \right] l = a l \cdot \frac{h+h'}{2}$$

Der Inhalt der beiden abgekürzten Pyramiden unter Voraussetzung n füssiger Böschung.

$$2 \left[\frac{1}{3} \frac{n \cdot h^2}{2} \cdot \left(l + \frac{lh'}{h-h'} \right) - \frac{1}{3} \frac{h'^2 n}{2} \cdot \left(\frac{l \cdot h'}{h-h'} \right) \right] = \frac{n \cdot l}{3 \cdot (h-h')} \cdot (h^3 - h'^3)$$

Wird nun zur Vereinfachung des Ausdrucks und Erlangung von Verhältnisszahlen für die Einheiten die Länge des Körpers l gleich Einer Ruthe von 12 Fuss, die Kronenbreite a gleich Einen Fuss, die Böschung einfüssig, also n gleich Eins angenommen, so ergibt sich der körperliche Inhalt in Schachtruthen zu 144 Kubikfuss:

a) für den Mittelkörper $= \frac{h+h'}{24}$

b) für beide Seitenkörper $= \frac{h^3 - h'^3}{36(h-h')}$

Die Höhen beziehungsweise Tiefen h und h' sind in den Tafeln von 0 bis 60 Fuss und zwar von Viertel zu Viertel Fuss steigend, derart zusammengestellt, dass für jede Kombination zweier, innerhalb dieser Grenzen fallenden Auf- oder Abtrags-höhen die nach vorstehenden Formeln berechneten Werthe für a und b gefunden werden können. Durch die Sonderung der Verhältnisszahlen a und b (denn nur solche sind es) für den Inhalt des Mittel- und der beiden Seitenkörper ist es thunlich gemacht, denselben für jede beliebige Kronen- beziehungsweise Sohlenbreite und für jedes Böschungs-Verhältniss genau zutreffend zu ermitteln.

Die Breite des Mittelkörpers ist in den Tafeln deshalb zu Einem Fuss angenommen worden, damit das Produkt der Verhältnisszahl a mit der wirklichen Breite der Krone oder Sohle den Inhalt dieses Körpers in Schachtruthen angiebt.

Ebenso verhält es sich mit den Seitenkörpern; die Verhältnisszahl b derselben ist, unter Annahme einfüssiger Böschung in den Tafeln berechnet, dieselbe giebt daher den richtigen Werth, wenn die Böschungen einfüssig sind; es leuchtet aber ein, dass für jedes andere Böschungs-Verhältniss der entsprechende Inhalt gefunden wird, wenn der Werth für b mit der massgebenden Böschungs-Verhältnisszahl z. B. $\frac{3}{4}$, $1\frac{1}{2}$, 2, für $\frac{3}{4}$, $1\frac{1}{2}$ und 2füssige Böschungen multiplicirt wird.

Da die Tafeln einen zu grossen Umfang erhalten haben würden, wenn die Höhen oder Tiefen der Aufträge von Zoll zu Zoll aufgenommen worden wären, so ist es für ausreichend erachtet worden, dieselben von 3 zu 3 Zoll abstufen zu lassen. Wenn daher die, aus dem Nivellement des Planums und der Neigung der Oberfläche des Körpers berechneten genauen Höhen in solcher Art reduzirt werden, dass sie auf 3, 6, 9 und 12 Zoll abschliessen, wobei Werthe unter $1\frac{1}{2}$ Zoll unberücksicht bleiben, Werthe über $1\frac{1}{2}$ Zoll für 3 Zoll voll gerechnet werden, so ergeben sich im Ganzen so geringe Abweichungen vom wirklichen Werthe, dass sie für die praktische Anwendung unberücksichtigt bleiben können.

Dagegen sind, weil beim Gebrauch der Tafeln die Verhältnisszahl a fast immer mit einer grösseren Ziffer multipliziert wird, als die für b , zur Erlangung einer möglichst gleichmässigen Schärfe in den Resultaten, die erstere mit 3 die letztere dagegen nur mit 2 Dezimalstellen berechnet worden.

Beim Gebrauch dieser Tafeln ist demnach folgende Regel anzuwenden:

Die beiden den Körper begrenzenden Höhen oder Tiefen eines Auf- oder Abtrages werden in den Tafeln, eine im Kopfe, die andere in den mit h bezeichneten Vertikalspalten, aufgesucht, und die zugehörigen Verhältnisszahlen, a der Mittel- b der Seitenkörper ausgeschrieben. Die Verhältnisszahl a wird mit der Breite des Mittelkörpers in Fuss, die der Seitenkörper mit der Böschungs-Verhältnisszahl multipliziert. Beide Werthe addirt und mit der Entfernung der Höhepunkte in Ruthen multipliziert, giebt den kubischen Inhalt des ganzen Körpers in Schachtruthen.

Beträgt z. B. die Höhe eines Dammes von 25 Fuss Kronen-

breite und $1\frac{1}{2}$ füssiger Böschung von 10 Ruthen Länge, an einem Ende 15.25, am anderen 23.75 Fuss, so ergiebt sich:

die Verhältnisszahl a für den Mittelkörper	1.625
„ „ „ b „ die Seitenkörper	32.19
der Werth a mit 25 multipliziert geben	40.625
„ „ „ b „ 1.5 „	48.285
zusammen	<u>88.910</u>

diese Summe mit 10 Ruthen Länge multipliziert, giebt den körperlichen Inhalt zu 889.10 Schachtruthen.

In der Ausübung wird nur selten ein solcher einzelner Körper, sondern gewöhnlich eine Reihe aufeinanderfolgender, von gleicher Kronenbreite, Böschung und Länge zur Berechnung kommen.

In solchen Fällen gewährt es eine Erleichterung, dass die Verhältnisszahlen zweier aufeinander folgender Körper auf derselben Seite der Tafel gefunden werden, also nur ein einmaliges Aufschlagen erfordern und dass sämtliche gefundene Verhältnisszahlen a und b summirt werden können, worauf mit dieser Summe, wie oben gezeigt, verfahren wird.

Einige Beispiele werden dies Verfahren anschaulicher machen:

- 1) Es soll der körperliche Inhalt der Erdmasse gefunden werden, welche aus einem Einschnitt nach nebenstehendem Längeprofil erfolgt, wenn die Sohlenbreite 24 Fuss beträgt, die Seitenwände $2\frac{1}{2}$ füssig abgeböschet werden sollen.

Die gegebenen Einschnittstiefen liegen in gleichmässigen Entfernungen von 10 Ruthen.

Die Rechnung wird am bequemsten in tabellarischer Form geführt, nach folgendem Schema:

Tiefen an den Grenzen der Ausschnitte	Verhältnisszahlen		
	<i>a</i> für den Mittelkörper	<i>b</i> für beide Seitenkörper	
0.00	}	0.344	1.89
8.25			
8.00	}	0.677	5.50
10.50			
11.75	}	0.771	7.17
9.50			
8.00	}	0.927	10.32
5.75			
0.00	}	0.885	9.44
	}	0.729	6.40
	}	0.573	3.97
	}	0.240	0.92
Summa		5.146	45.61
multipliziert mit 24		24	2.5
resp. 2½ =		20.584	22.805
		102.92	91.22
		123.504	114.025
			123.504
	Summirt		237.529

Mit der Entfernung der einzelnen Punkte
= 10 Ruthen multipliziert, giebt den Inhalt
= 2375.29 Schachtruthen.

In die erste der drei Spalten vorstehender Tabelle, werden der Reihe nach, mit Null anfangend, die Tiefen des Einschnitts eingeschrieben, während durch die beiden anderen Spalten so liniirt wird, dass eine Zahlenreihe auf die Mitte je zweier in der ersten Spalte zutrifft.

In den Tafeln wird nun eine der beiden zusammengehörenden Zahlen im Kopfe, die andere in einer der Vertikalspalten *h* aufgesucht. Neben der letzteren finden sich die beiden Verhältnisszahlen *a* und *b*, welche in die betreffenden Spalten der Berechnungstabelle überschrieben werden.

Nachdem in solcher Art das ganze Profil durchgegangen ist,

werden die Verhältnisszahlen a und b abgesondert addirt. Für erstere ist in dem gegebenen Beispiel die Summe 5.146, für die andere 45.61. Von diesen Summen wird die erste a für den Mittelkörper mit der Sohlenbreite 24, die andere für beide Seitenkörper mit der Verhältnisszahl der Böschung = 2.5 multipliziert. Das Produkt für a ist = 123.504 für b = 114.025, beide addirt geben 237.529, welche Zahl mit der konstanten Entfernung der einzelnen Punkte von einander = 10 Ruthen multipliziert, die Zahl der Schachtruthen, welche dieser Einschnitt enthält, zu 2375.29 ergibt.

- 2) Es soll der körperliche Inhalt der Erdmasse gefunden werden, welche erforderlich ist, um einen Damm von 25.62 Fuss Kronenbreite, auf der einen Seite $1\frac{1}{2}$, auf der anderen 2füssig geböschet, nach dem hierunter angegebenen Längeprofil, anzuschütten.

Hier, wo die Entfernungen der gegebenen Höhepunkte von einander nicht gleich sind, müssen die, für die einzelnen Abtheilungen des Damms gefundenen Verhältnisszahlen a und b vorab mit den zugehörigen Längen in Ruthen multipliziert werden.

Demnächst werden diese Produkte für den Mittel- und die Seitenkörper getrennt, summirt, erstere Summe mit der Kronenbreite = 25.62 Fuss, letztere mit der mittleren Verhältnisszahl beider Böschungen $\frac{2+1.5}{2} = 1.75$ multipliziert. Die Summe dieser beiden Produkte giebt den körperlichen Inhalt des ganzen Damms zu 3477.41 Schachtruthen.

Das Verfahren ist aus der folgenden Berechnungstabelle ersichtlich:

Höhe	Verhältnisszahlen für die Einheit		Länge der Station Ruthen	Verhältnisszahlen für die wirkliche Länge	
	<i>a</i>	<i>b</i>		<i>a</i>	<i>b</i>
0.00	} 1.187	22.56	12	14.244	270.72
28.50					
26.00	} 2.271	61.92	5	11.355	309.60
20.75					
4.50	} 1.948	45.72	8	15.584	365.76
8.25					
0.00	} 1.052	15.12	6	6.312	90.72
0.00					
	} 0.531	3.48	8.5	4.514	29.58
	} 0.344	1.89	23	7.912	43.47
Summa				59.921	1109.85
Multipliziert mit				25.62	1.75
giebt die Produkte				1535.18	1942.23
dieselben addirt				1942.23	
geben den Inhalt zu				3477.41	Schachtruthen

Die Resultate dieser Berechnungsart sind aber, wie schon Eingangs erwähnt, nur vollkommen richtig, wenn die Lage der zu beschüttenden oder abzugrabenden Boden-Oberfläche, rechtwinklicht auf die Richtung der Längensaxe, als horizontal angenommen werden kann; sie weichen aber um so mehr von der Wahrheit ab, je mehr sich dieselbe geneigt findet.

Bei ganz generellen Ueberschlägen wird zwar in der Regel von diesen Differenzen abgesehen, allein bei Spezial-Arbeiten dürfen sie nicht vernachlässigt werden, weshalb, um auch in solchen Fällen die Tafeln noch benutzen zu können, ein Ausdruck gesucht ist, welcher die Abänderungen der Verhältnisszahlen *a* und *b* bei einem Querabhange des Terrains angiebt.

Von unbedeutenden wellenförmigen Bewegungen der Bodenfläche in dieser Richtung kann füglich abgesehen werden und der mittlere Abhang durch $\frac{1}{m}$: nämlich dass er auf *m* Fuss Breite einen Fuss abfällt: ausgedrückt werden.

Wird nach nebenstehender Figur die obere Damm- oder untere Einschnittsbreite mit $2B$, die Höhe (beziehungsweise Tiefe) in der Mittellinie mit h bezeichnet, die Damm- oder Einschnittsböschung n füssig angenommen, so ergibt sich der Flächen-Inhalt des mittleren trapezförmigen Theiles des Quereinschnitts zu

dies ist derselbe Werth, nach welchem die Verhältnisszahlen a des Mittelkörpers in der Tabelle berechnet sind. In Bezug auf diesen leidet daher die Anwendung derselben keine Beschränkung. Nicht so ist es mit den pyramidalen Seitenkörpern, die unter diesen Umständen nicht mehr gleich sind und deren Inhalte bei verschiedenen Böschungsanlagen nicht nach der einfachen Verhältnisszahl zu- oder abnehmen.

$$B \left[\frac{h + h + \frac{B}{m}}{2} \right] + B \left[\frac{h + h - \frac{B}{m}}{2} \right] = 2.Bh$$

Die beiden mit I und II bezeichneten Dreiecke bilden jedes die Basis einer Pyramide von den Höhen L und L' ; welche mit ihren Spitzen im Terrain an den Punkten auslaufen, wo $\left[h + \frac{B}{m} \right]$ und beziehungsweise $\left[h - \frac{B}{m} \right] = 0$ werden. —

Aus der vorstehenden Figur ergibt sich die Höhe des Dreiecks I , also $y = \frac{n[mh + B]}{m - n}$, und die Höhe des Dreiecks II , d. h.

$x = \frac{n[mh - B]}{m + n}$, es ist demnach der Inhalt der Pyramide

$$\text{auf } I = \frac{L}{6} \left[h + \frac{B}{m} \right] \cdot \frac{n[mh + B]}{(m - n)} = \frac{L}{6} \frac{n}{m} \frac{[mh + B]^2}{(m - n)}$$

$$\text{und auf } II = \frac{L'}{3} \cdot \frac{1}{2} \left[h - \frac{B}{m} \right] \cdot \frac{n[mh - B]}{(m + n)} = \frac{L'}{6} \frac{n}{m} \frac{[mh - B]^2}{(m + n)}$$

Gewöhnlich wird aber der Werth für abgekürzte Pyramiden gefordert, so dass von den vorstehenden Werthen die Inhalte der nach den Spitzen zu liegenden Theile in Abzug gebracht werden müssen. Gehört nun der zweite [kleinere] Schnitt einer Höhe

h' an, so ergibt sich der Inhalt der beiden Spitzen, deren Höhe für diesen Schnitt als Basis mit z und z' bezeichnet werden mögen

$$= \frac{z}{6} \cdot \frac{n [mh' + B]^2}{m [m - n]}$$

$$\text{und} = \frac{z'}{6} \cdot \frac{n [mh' - B]^2}{m [m + n]}$$

die Inhalte der abgekürzten Pyramiden sind gleich den Differenzen dieser und der obigen Ausdrücke. Es ist daher die grössere der beiden abgekürzten Pyramiden mit dem Dreieck I als Basis, die mit P_1 bezeichnet werde

$$P_1 = \frac{n}{6m [m - n]} [L \cdot [mh + B]^2 - z [mh' + B]^2]$$

und die kleinere P_2 auf II

$$P_2 = \frac{n}{6m [m + n]} [L' \cdot [mh - B]^2 - z' [mh' - B]^2]$$

Wird die, beiden Körpern P_1 und P_2 gemeinsame Länge $L - z = L' - z'$ mit l bezeichnet, so bestimmen sich die Werthe der vier Längen L , L' und z , z' aus den Proportionen

$$L : z = \left[h + \frac{B}{m} \right] : \left[h' + \frac{B}{m} \right]$$

$$\text{und } L' : z' = \left[h - \frac{B}{m} \right] : \left[h' - \frac{B}{m} \right].$$

Es ergibt sich hieraus

$$L = \frac{l [mh + B]}{m [h - h']}$$

$$z = \frac{l [mh' + B]}{m [h - h']}$$

$$L' = \frac{l [mh - B]}{m [h - h']}$$

$$z' = \frac{l [mh' - B]}{m [h - h']}$$

Werden diese Werthe in die obigen Ausdrücke für P_1 und P_2 eingesetzt, darauf beide Gleichungen addirt und geordnet, so erhält man für den Inhalt beider Böschungskörper zusammen den Ausdruck:

$$P_1 + P_2 = l \left[\frac{n \cdot m^2}{m^2 - n^2} \cdot \frac{h^3 - h'^3}{3 [h - h']} + \frac{2 \cdot n^2}{m^2 - n^2} \cdot B \cdot \frac{h + h'}{2} + \frac{n}{m^2 - n^2} \cdot B^2 \right]$$

Wird die Länge L wie gewöhnlich in Ruthen angegeben, so ergibt der vorstehende Ausdruck den Inhalt in Schachtruthen, wenn er durch 12 dividirt wird. Er nimmt dann die Form an:

$$P_1 + P_2 = P = l^0 \left[\frac{nm^2}{m^2 - n^2} \cdot \frac{h^3 - h'^3}{36 [h - h']} + \frac{2n^2}{m^2 - n^2} \cdot B \cdot \frac{h + h'}{24} + \frac{n}{12 [m^2 - n^2]} B^2 \right]$$

Nun ist bekanntlich

$\frac{h^3 - h'^3}{36 [h - h']}$ der Werth für die Verhältnisszahl b in den Tafeln, für die Endhöhen h und h' , und

$\frac{h + h'}{24}$ der Werth der Verhältnisszahl a in den Tafeln für dieselben Höhen. Wird diese Bezeichnung in vorstehende Gleichung eingeführt, so folgt:

$$P = l^0 \left[\frac{n \cdot m^2}{m^2 - n^2} \cdot b + \frac{2 \cdot n^2}{m^2 - n^2} \cdot B \cdot a + \frac{n}{12 [m^2 - n^2]} \cdot B^2 \right]$$

Für den praktischen Gebrauch lässt sich dieser Ausdruck noch bedeutend vereinfachen, wenn für die am häufigsten vorkommenden Verhältnisse besondere Hülftafeln berechnet werden.

Dies geschieht unter der Voraussetzung, dass die Werthe von n und m zwischen gewissen engen Grenzen liegen und für bestimmte Anlagen B nicht häufig wechselt.

Wird in Erwägung gezogen, dass die Böschungs-Verhältnisse von Auf- und Abträgen in den allermeisten Fällen zwischen $\frac{1}{4}$ und 4 liegen, ferner, dass auf Seitenabhängen, welche stärker als $\frac{1}{3}$ fallen, nicht mehr ohne künstliche Unterstützungen gearbeitet zu werden pflegt, und dass bei Neigungen von weniger als $\frac{1}{20}$ der Werth aus den Tafeln für die Praxis hinreichend genaue Werthe giebt, so fällt n zwischen 0.25 und 4, m zwischen 3 und 20.

Werden zur Vereinfachung der Form die Coefficienten des obigen Ausdrucks

$$\frac{nm^2}{m^2 - n^2} \text{ mit } \alpha, \frac{2n^2}{m^2 - n^2} \text{ mit } \beta, \frac{n}{12 [m^2 - n^2]} \text{ mit } \gamma$$

bezeichnet, so ist der Inhalt der Böschungsprismen

$$P = l^0 [\alpha \cdot b + \beta \cdot B \cdot a + \gamma \cdot B^2] \text{ in Schachtruthen.}$$

Die nachstehende für jede beliebige Kronen- oder Sohlenbreite geltende Hülftafel giebt die Werthe dieser 3 Coefficienten $\alpha \beta \gamma$ für die verschiedenen hier in Betracht kommenden Combinationen der m und n .

[Siehe die nebenstehende Hülftafel A.]

Der Gebrauch nebenstehender Hülftafel ist folgender:

Man entnehme für die gegebenen Höhen h und h' aus der Erdberechnungstabelle die beiden Werthe b und a , multiplizire jenen mit dem bezüglichen Coefficienten α aus der Hülftafel, diesen mit dem Coefficienten β und der halben Kronen- [oder Sohlen-] breite B , endlich den Coefficienten γ mit dem Qua-

HÜLFSTAFEL

zur Berechnung der Böschungskörper bei geneigtem Terrain.

Es ist $\alpha = \frac{n \cdot m^2}{m^2 - n^2}$; $\beta = \frac{2 \cdot n^2}{m^2 - n^2}$; $\gamma = \frac{n}{12(m^2 - n^2)}$.

m	n = 0.25			n = 0.333			n = 0.5			n = 0.667			n = 0.75			n = 1.0			n = 1.25			n = 1.333			n = 1.5			n = 1.75			n = 2.0			n = 2.5			n = 3			n = 4

drate $[B^2]$ der halben Kronen- [oder Sohlen-] breite, die Summe dieser 3 Produkte mit der in Ruthen ausgedrückten Entfernung $[l]$ der beiden Profile für die Höhen h und h' multipliziert, giebt den Gesamtinhalt beider Böschungskörper in Schachtruthen.

Wenn für eine bestimmte Anlage die Kronenbreite der Aufträge oder die Sohlenbreite der Einschnitte, also $2B$ constant bleibt: so führt man in die Hülftafel anstatt der einfachen Coefficienten β und γ die Produkte $\beta \cdot B = \beta'$ und $\gamma \cdot B^2 = \gamma^1$ ein, dann ist die Manipulation ausserordentlich einfach; die Formel geht dann über in

$$P = l^0 [a \cdot b + \beta' \cdot a + \gamma^1]$$

wofür b und a aus der Haupttafel und a , β^1 , γ^1 aus der Hülftafel entnommen werden.

Ein Beispiel des Gebrauchs der Tafel wird die Erleichterung, welche die Anwendung gewährt anschaulich machen.

Eine 10 Ruthen lange Dammabtheilung bei 26 Fuss Kronenbreite, liegt an einem Ende 12.5, am anderen 8.75 Fuss über dem natürlichen Boden, welcher ein Seitengefälle von 1:5 besitzt. — Der Dammkörper soll $1\frac{1}{2}$ füssige Böschungen erhalten.

Es ist also $B = 13$, $h = 12.5$, $h' = 8.75$, $m = 5$, $n = 1.5$ und die Länge des Dammkörpers $l = 10$ Ruthen. Die Verhältnisszahlen aus der Tabelle sind $a = 0.885$ und $b = 9.51$.

Der Mittelkörper des Dammes ist daher für 10 Ruthen Länge $= 10 \cdot 26 \cdot 0.885 \dots \dots \dots = 230.1$ Schachtruthen und die Böschungskörper nach obiger Formel

$$P = l [a \cdot b + \beta \cdot B \cdot a + \gamma \cdot B^2]$$

$$P = 10 [1.65 \cdot 9.51 + [0.1978 \cdot 13] \cdot 0.885 + [0.0055 \cdot 169]] =$$

$$10 [1.65 \cdot 9.51 + 2.571 \cdot 0.885 + 0.93] = 188.96 \quad - \quad -$$

daher der ganze Inhalt des Dammes $= 419$ Schachtruthen. Eine für 26 Fuss Kronenbreite umgerechnete Hülftafel würde den Werth der drei Coefficienten

$$a = 1.65, \beta^1 = 2.571 \text{ und } \gamma^1 = 0.93$$

unmittelbar angeben.

Erhalten die Damm- oder Einschnitts-Böschungen Bankette, so kommt ein mittleres Böschungs-Verhältniss in Anwendung, welches unter Berücksichtigung der Gesamtausladung zu bestimmen ist.

Wird z. B. bei Einschnitten mit $1\frac{1}{2}$ füssigen Böschungen auf je 6 Fuss Höhe ein $1\frac{1}{2}$ Fuss breites Bankett angelegt, so ist n nicht 1.5, sondern es bestimmt sich die mittlere Böschung durch eine von der Sohlen- nach der oberen Kante des Einschnitts gezogene Linie. Auf je 6 Fuss Höhe erhält die Böschung in diesem Falle $10\frac{1}{2}$ Fuss Ausladung und n wird daher 1.75.

Schliesslich wird noch zur mehreren Deutlichkeit, hinsichtlich Einrichtung der Arbeit als Beispiel eine Erdberechnung für wechselnden Auf- und Abtrag mitgetheilt unter Zugrundelegung der Annahme, nicht gleichmässiger Entfernung der Höhenpunkte, 2 füssiger Böschung, der in der Sohle 42 Fuss breiten Einschnitte und $1\frac{1}{2}$ füssiger, der in der Krone 26 Fuss breiten Aufträge.

[Siehe die nebenstehende Berechnung B.]

(The following text is a mirror image of the page's content, appearing as bleed-through from the reverse side. It contains mathematical formulas and descriptive text.)

... die Länge des Dammkörpers = 10 Ruten. Die Verhältnisszahl
 den aus der Tabelle sind $a = 0.885$ und $b = 0.21$.
 Der Mittelkörper des Damms ist daher für 10 Ruten Länge
 = 10.26 0.885 = 9.057
 = 230.1. Schachteln
 und die Hochwasserkörper nach obiger
 Formel

$$P = (a + b \cdot a + y \cdot b^2)$$

$$P = 10 [1.65 \cdot 0.21 + (0.1978 \cdot 13) \cdot 0.885$$

$$+ [0.0025 \cdot (89)] =$$

$$10 [1.65 \cdot 0.21 + 2.571 \cdot 0.885 + 0.93] = 188.98$$
 daher der ganze Inhalt des Damms = 419 Schachteln.
 Eine für 26 Fuss Kronenbreite umgerechnete Hilfs-tafel würde
 den Werth der drei Coefficienten
 $a = 1.65, b = 2.571$ und $y = 0.02$
 unmittelbar angeben.
 Erhalten die Damm- oder Einschnitts-Böschungen Bankette,
 so kommt ein mittleres Böschungs-Verhältnis in Anwendung
 welches unter Berücksichtigung der Gesamtausladung zu be-
 stimmen ist.
